UC San Diego | JACOBS SCHOOL OF ENGINEERING | September 5, 2025

# Goals

## Must have

Autonomous Lane Tracking

Stop at a Safe Distance

Object Recognition

## Nice to have

React Based on Object Type

- If person - Wait until path is clear
- If object(e.g. bottle) - find new path

# Demonstration

## Challenge 1: Person + Bottle

## Challenge 2: Multi-Object

# rqt\_graph - Outside Dangerous Range

**lane\_detection\_node:** Detects lane lines and publish centroid of the lane

**lane\_guidance\_node :** Applies PID control on tracking error to compute steering and throttle

**safety\_stop\_node:** Subscribes to LiDAR scan and stop the car in certain range

**vesc\_twist\_node:** Converts values into motor commands for the VESC

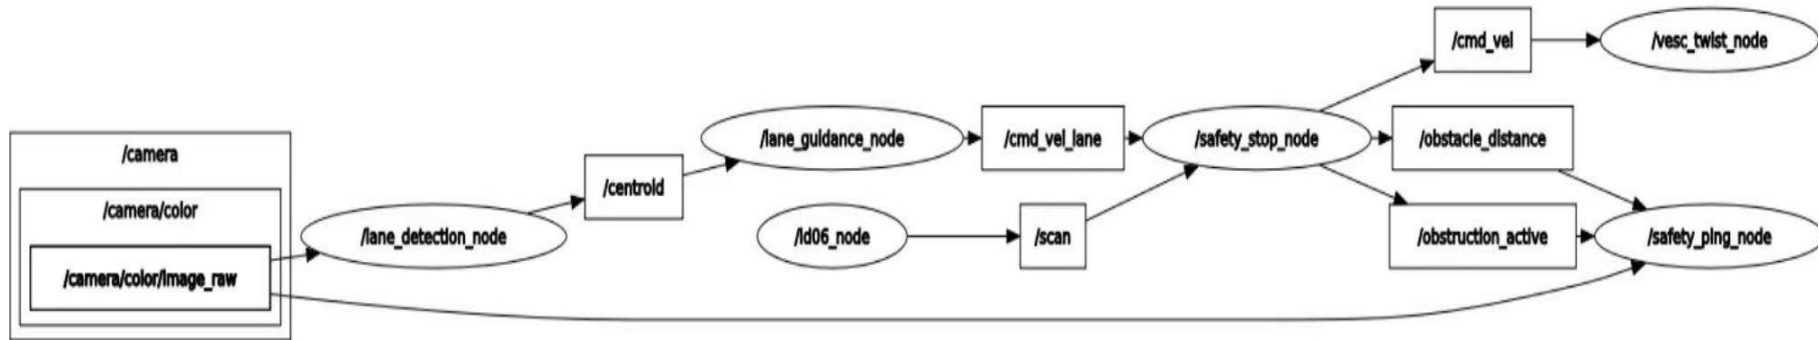

# rqt\_graph - Inside Dangerous Range

**Id06\_node:** Publish Lidar scan data to safety\_stop\_node

**safety\_stop\_node:** Send message to vesc\_twist\_node stop. Tell safety\_ping\_node to run object detection.

**safety\_ping\_node:** Subscribes to image\_raw, if obstruction\_active, run objection detection model.

# Hardware

20° Camera Mount with  
GPS/LiDAR Stand

Mounting Plate  
20×10mm Hole Spacing

Jetson Nano Case

# Discussion

## Camera Angle

Angle > 15 degree improves lane detection

But limits object recognition due to height and range

Lane visibility vs Detection accuracy

960x960 (no detections),

## Model Accuracy

## LiDAR Position

# If We Have More Time (or Money)

## Add Camera

1 for lane following

1 for object recognition

## LiDAR Reposition

Adjust height and angle

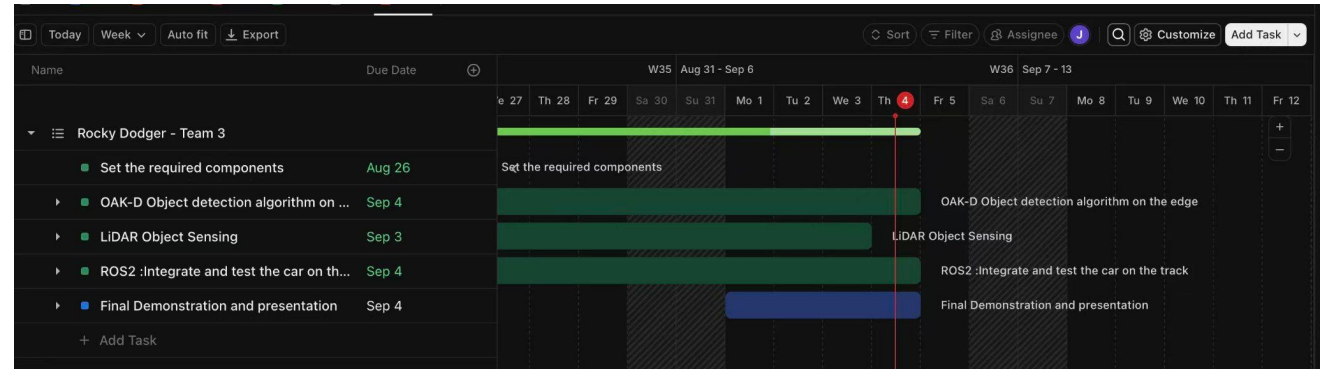

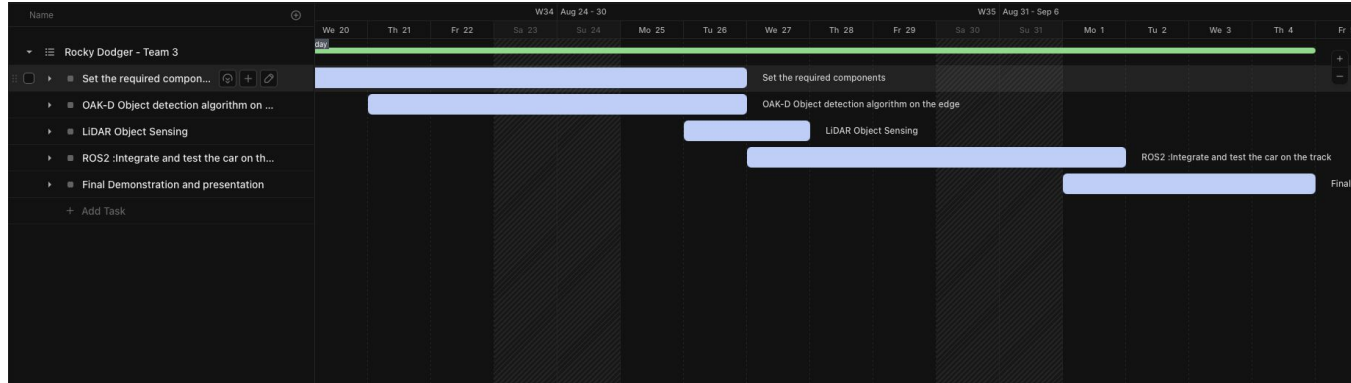

## React Based on Object Type

Find new path, change lane

# Gantt Chart - current status

**Thank you!**
